ABSTRACT

A study has been carried out to investigate the physicochemical, binding and disintegrating properties of starch isolated from powder of *Musa paradisiaca* (Family: Musaceae). The studies indicated that this starch is qualitatively and quantitatively comparable to Corn starch as also the rheological and swelling characteristics. Paracetamol (500mg) tablets prepared using Corn and *Musa paradisiaca* starch met the requirements of uniformity of weight, assay, friability and hardness. These tablets also conformed to the disintegration and dissolution specifications of Indian Pharmacopoeia. *Musa paradisiaca* starch showed adequate binding and disintegrating characteristics.

Key Words: *Musa paradisiaca* Starch, Banana Starch, Corn Starch, Paracetamol, Physicochemical properties, Dissolution, Binding and Disintegrating properties.

INTRODUCTION

*Musa paradisiaca* is also known as Banana, ‘Vazhai pazham’ in Malayalam and Tamil. The chief producing states in India are Kerala, Tamilnadu, Karnataka and Andhra Pradesh. The powder contains starch as chief carbohydrate. The powder contains carbohydrate. The powders are edible and contain 20-60% starch [1,2]. Starches are used as multifunctional excipient in the field of pharmaceutical sciences.
The present work deals with isolation of starch from *Musa paradisiaca* powder and comparison of its physicochemical, binding and disintegrating properties with Corn starch which is being abundantly used.

**EXPERIMENTAL SECTION**

**Material:**
Paracetamol (Wallace Pharmaceutical Pvt.Ltd, Goa), *Musa paradisiaca* powder (Procured from local market), Corn starch (Durga chemical laboratories). All other chemicals were of analytical grade were obtained from Qualigens fine chemicals, Mumbai.

**Method of Extraction:**
The method of extraction of starch from the *Musa paradisiaca* powder is reported in literature [1, 2] but in order to improve the quality of starch the method was modified as follows:

i) Fresh unpeeled banana (*Musa paradisiaca*, family: Musaceae) were collected and washed it thoroughly with water.

ii) Then the banana were cut into small pieces using a sharp knife and minced in mixer using 0.05N sodium hydroxide.

iii) Then slurry was then filtered through muslin cloth. The filtrate was allowed to stand for one hour and settled starch was washed repeatedly with water to remove alkali completely.

iv) It was dried in air. The pulp remaining on cloth was again suspended in 0.05N sodium hydroxide and filtered through muslin cloth till no milky filtrate was obtained.

v) Then the dried powder was then passed through sieve number 40 and stored in an airtight container.

**Physicochemical properties:**
Extracted starch and Corn starch were studied for microscopic characteristics [3], Loss on drying [4], Acidity[4], pH[5], Ash value[6], Bulk Density[7], Angle of repose [8], and compressibility index[8].

**Rheological studies of Starch mucilage:**
Starch mucilage (5% and 10%) of *Musa paradisiaca* and Corn were prepared. The rheological characteristics of mucilages were evaluated by using Brookfield viscometer.

**Swelling characteristics:**
Swelling characteristics of the starches were studied at different temperatures by microscopic method. The extend of swelling was calculated by finding the ratio between grain size at the maximum temperature and at 35°C.

**Formulation of Tablets:**
Six formulations of Paracetamol (500mg) tablets containing 2.5%, 5.0% and 10% of *Musa paradisiaca* starch and Corn starch as a disintegrant were prepared. Paracetamol granules were prepared using 10% w/w paste of Corn starch as well as *Musa paradisiaca* starch by wet granulation method was found that good charecteristic(compactness and binding properties). Lubricated granules were compressed by using single punch tablet machine (Cadmach, Ahmedabad).
Evaluation of Granules

Bulk density ($D_b$):
It is ratio of total mass of powder to the bulk volume of powder. 10 gm of drug excipient mixture
were taken and transferred into a 50 ml measuring cylinder and the volume was noted. The bulk
density of the powder were expressed in gm/ml was determined as follows.

$$D_b = \frac{M}{V_o}$$

Where,
- $M$ is the mass of the powder
- $V_o$ is the bulk volume of the powder.

Angle of repose:
The frictional forces in a loose powder can be measured by the angle of repose, $\theta$. This is the
maximum angle possible between the surface of a pile of powder and the horizontal plane and it
is given as,

$$\tan \theta = \frac{h}{r}$$

$$\theta = \tan^{-1} \left( \frac{h}{r} \right)$$

Where
- $\theta$ is the angle of repose
- $h$ is the height in cm
- $r$ is the radius.

The powder mixture was allowed to flow through the funnel fixed to a stand at definite height.
The angle of repose was then calculated by measuring the height and radius of the heap of
powder formed.

Test for friability and flow properties of granules:
Paracetamol granules prepared with *Musa paradisiaca* starch and Corn starch were tested for
friability and flow properties. Friability testing was carried out using Roche friabilator. Friability
was calculated from the following formula

$$\% \text{ Friability} = \left( 1 - \frac{W_1}{W_2} \right) \times 100$$

Where,
- $W_1$ = weight of granules after test.
- $W_2$ = weight of granules before test.

Flow properties of granules were tested by determining angle of repose [8].

Evaluation of Tablets

Hardness and friability tablets [9]:
Hardness and Friabilator testing were carried out by using Monsanto hardness tester and
Roche friabilator respectively.

Uniformity of weight [10]:
The weight variation test of the tablets was performed as per I.P. Twenty tablets of each type
were weighed and average weights were calculated.

Thickness of tablets:
The thickness of six tablets was measured using Vernier calipers. The extent to which the
thickness of each tablet deviated from $\pm 5\%$ of the standard value was determined. Six tablets
from each batch were selected and evaluated, and the average value with standard deviation was
recorded.
Disintegration Test:
All the six formulations were tested for disintegration time as per method prescribed in I.P. for uncoated tablets [10].

Assay:
Assays were carried out by using the method prescribed in I.P [11].

Dissolution studies:
Dissolution studies were performed as per procedure given in I.P [11]. The sampling time specified in I.P. The sampling time specified in I.P. was modified instead of withdrawing a single sample after 30 minutes; serial sampling was done at 5, 10,15,20,25 and 30 minutes.

RESULTS AND DISCUSSION
Starch extracted from *Musa paradisiaca* had a light brownish tinge hence bleaching was carried out with water. On dry basis 20-60% starch was obtained. Grains of *Musa paradisiaca* starch were found to be smaller in size than of Corn starch. They were round, granular in shape. Not much difference was observed in loss on drying, acidity, ash value, pH values of *Musa paradisiaca* starch and Corn Starch. The loss on drying and acidity values was well within official limit Table 1. The bulk density, angle of repose and compressibility index of both starches was comparable Table 1.

*M.P. - Musa Paradisiaca*

Rheological both starches showed Non-Newtonian behavior with shear thinning properties. Swelling Characteristics studies revealed that swelling ratio of *Musa paradisiaca* starch is slightly greater than that of Corn starch Table 2. It showed that *Musa paradisiaca* starch may exhibit good disintegrating property over corn starch. This disintegrating property may be attributed to the more number of starch grains per mg of sample.

Swelling ratio: 2.124 (M.P.), 2.037 (Corn)

The friability testing of granules showed that the Corn starch had slightly high binding strength than that of *Musa paradisiaca* starch Table 3. In all the cases the values of angle of response were ≤30°, which indicate that both the starches were free flowing. Hardness and % friability of the tablets were found to be well within acceptable limits Table 3.

C- Containing Corn Starch as binder and disintegrant

The study of disintegrating property of all the formulations showed that the disintegration time for the tablets prepared with *Musa paradisiaca* starch was less than that of Corn starch Table 5
reflecting its good disintegrating characteristic. One point dissolution data of all the tablets prepared with both the starches conform to dissolution specifications of I.P.

**CONCLUSION**

There is an excellence scope for Musa paradisiaca starch. Hence newer natural substance must be studied for its pharmaceutical application. Musa paradisiaca starch could be used as a promising pharmaceutical excipient in tablet technology as, it showed adequate binding and disintegrating properties.
