

## Associated Impacts the Participant with Two Kinds of Worms (Cestoda) *Raillietinacesticillus* and (Nematodes) *Ascaridiagalli* in Domestic Chickens

Sukayna Jabbar Mushattat

College of Nursing, Karbala University, Iraq

### ABSTRACT

Twenty domestic chickens infected with two types of severe Cestoda and Nematoda examined in the veterinary hospital in Najaf province / Iraq for the period from the March until July 2016. Haematological and serum biochemical parameters were measured in the samples collected. Variations in the levels of these parameters were determined. The parameters measured showed significant lowest variations in infected chickens compare with non-infected chickens. These include RBC, PCV, Hb, MVC, MCH, MCHC, Na<sup>+</sup>, K<sup>+</sup>, Ca, CL, ALP, GPT, GOTM and Creatinine. The parameters measured of WBC showed highest significant variations in infected chickens compare with non-infected chickens. The pathological changes represented a clear macroscopic swelling and swelling of the duodenum, while histological changes Was very clear and is represented by the occurrence of inflammation of the epithelial layer is accompanied by a massive infiltration of cells Inflammatory injury and epithelial disjointed cells. Occurrence of macular show caused by the presence Parasite in the intestine leads to the disintegration of the villi where the exits, look devoid of the original features of any erosion of epithelial cells lining the intestinal villi and glands.

### INTRODUCTION

Parasitism is one of the main problems that cause economic losses in domestic poultry, including growth retardation and weight loss, diarrhea and bowel obstruction and increase the rate of injuries [1-6]. Poultry exposed to nit internal and external parasites and worms are the most important internal worms are Cestoda (tapeworms) and Nematoda [7]. Characterized tapeworms as worms long flat compressed top and bottom, and these worms *Raillietinacesticillus* worm that lives in small intestines, causing several changes for the host, including general weakness and severe diarrhea and wasting and because of the diversity of chicken feed grain and worm the Land and insects in the clay material [5], so the chickens at risk of those phases misfortune of some parasitic worms and thus the growth of adult worms) [4]. Nematodes or roundworms are the most important group of helminth parasites of poultry. This is due to the large number of parasitic species that cause damage to the host, especially in severe infections. Roundworms are elongated, cylindrical and unsegmented [2]. They are covered with a tough, non-cellular layer called the cuticle. Roundworms have a well-developed alimentary tract [7]. *Ascaridiagalli* is a parasitic roundworm belonging to the phylum Nematoda.

The genus *Ascaridia* is essentially intestinal parasites of birds [10]. *A. galli* is the most prevalent and pathogenic species, especially in domestic fowl [1]. It causes ascaridiasis, a disease of poultry due to heavy worm infection, particularly in chicken and turkeys. It inhabits the small intestine, and can be occasionally seen in commercial eggs. Effects: Weight depression. In severe infections, intestinal blockage can occur. At high levels of infection, there is loss of blood, reduced blood sugar content, retarded growth and greatly increased mortality. Parasite can occasionally be seen in commercial eggs [10-17].

## MATERIALS AND METHODS

Were examined 80 from the local chicken, which was suffering from satisfactory injuries in the veterinary hospital for the period from March until July, and by laboratory testing of stool indicate the presence of 20 cases suffer from injury with two types of worms (tapeworms and nematodes).

About 2 ml of blood was collected through the jugular vein from each bird, 0.5 ml of which was dispensed into clean bijou bottles containing anticoagulant EDTA. The rest was allowed to clot [18]. The anticoagulated blood was used to determine red blood cell (RBC) count, packed cell volume (PCV), haemoglobin (Hb) concentration, and white blood cell (WBC) count. Serum was separated from the clotted blood following centrifugation at 3,000 r.p.m. for 10 minutes at room (28 C), and stored at - 20 C until required for other tests [12].

### Experimental procedure

Red and white blood cells were counted using the haemocytometer method, PCV by the microhaematocrit method, and Hb concentration by the cyanmethaemoglobin method. Mean corpuscular volume (MCV), MCH, and MCHC were calculated from the above as described by [12]. Serum sodium, potassium and calcium were determined with a flame photometer [17]. Serum enzymes glutamate pyruvate transaminase (GPT) and glutamate oxalate transaminase (GOT) were converted to oxoacids and then coupled to 2, 4, dinitrophenylhydrazine forming hydrazone, the intensity of the colour of which depends on the quantity of enzyme present [13]. The enzyme alkaline phosphatase and ALP were measured by a reaction which terminated in colour development measured at 500 nm wavelength [3]. Creatinine was determined using the standard Technicon methods of the analyser [18].

### Histological study

The pieces of small intestine were taken. These tissues were fixed in the "Bouins fluid" for 24 hours, dehydrated in the series of ascending grade of alcohol (70%, 80%, 90%, 95%, 100%), cleared in xylene, infiltrated in paraffin, embedded in paraffin and the paraffin blocks were sectioned at 6  $\mu$ m thickness using sliding microtome [19]. The sections were floated on luke-warm water in a floatation bath for stretching and then the paraffin sections were mounted on slides using an egg albumin and dried on slide warmer. The sections were then stained with standard Haematoxylin and Eosin method for general microscopic study [19] (Figures 1-4).

### Statistical analysis

Analysis was conducted using the method Least Significant Difference L.S.D of the experiment and the level of probability  $P < 0.05$  to find a moral differences between the rates of measurements used in this experiment.

## RESULTS

Red blood cell count, PCV and Hb concentration all varied in a similar pattern. As shown in table 1, mean value of RBC is significantly ( $P < 0.05$ ) it is  $2.22 \pm 0.2$  (10<sup>6</sup>/ul) less than non-infected chicken it was  $4 \pm 0.1$  (10<sup>6</sup>/ul). The mean value of PCV in infected was  $26.4 \pm 2.80\%$ . This is significantly ( $P < 0.05$ ) less than the value of Non-infected it was  $35 \pm 2.90\%$ . The Hb concentration of  $8.4 \pm 0.22$  mg/dl is significantly ( $P < 0.05$ ) less than Non-infected it was  $11 \pm 0.31$  mg/dl. Mean values of MCV ( $116.9 \pm 3.45$   $\mu$ m<sup>3</sup>), MCH ( $37.8 \pm 2.2$  p9) and MCHC ( $31.8 \pm 1.8$  g/dl) were lowest in infected and highest in non-infected significantly ( $P < 0.05$ ). White blood cells peak value in infected chickens  $116.3 \pm 2.93$  (10<sup>3</sup>/ul) higher than the value of non-infected it was  $100.1 \pm 2.82$  (10<sup>3</sup>/ul). A significant ( $P < 0.05$ ). Serum Na<sup>+</sup>, K<sup>+</sup>, Ca<sup>++</sup> and Cl<sup>-</sup>, ion concentrations also varied significantly ( $P < 0.05$ ). The serum electrolytes are significantly lowest than the value of non-infected chicken (Table 2). Among the enzymes measured, GOT is significantly lowest  $31.0 \pm 2.5$  IU/L than non-infected it was  $35 \pm 1.9$  IU/L. ALP is significantly ( $P < 0.05$ ) higher than the value of infected chicken  $164.8 \pm 23$  IU/L. The value of GPT is significantly ( $P < 0.05$ ) lower in infected chicken  $22.1 \pm 1.7$  IU/L than non-infected it was  $25 \pm 1.8$  IU/L. The concentration of Creatinine enzyme was  $0.91 \pm 0.20$  IU/L compare with non-infected it  $1.2 \pm 0.6$  IU/L. A significant ( $P < 0.05$ ) (Table 3)

**Table 1: Some haematological parameters in the infected, non-infected and local chickens**

Parameters	Infected	Non-infected	L.S.D
PCV (%0)	26.4 $\pm$ 2.80	35 $\pm$ 2.90	2.432
Hb (g/dl)	8.4 $\pm$ 0.22	11 $\pm$ 0.31	1.561
RBC (10 <sup>6</sup> /ul)	2.22 $\pm$ 0.2	4 $\pm$ 0.1	1.233
WBC (10 <sup>3</sup> /ul)	116.3 $\pm$ 2.93	100.1 $\pm$ 2.82	2.452
MCV ( $\mu$ m <sup>3</sup> )	116.9 $\pm$ 3.45	80 $\pm$ 2.6	2.336
MCH (p9)	37.8 $\pm$ 2.2	26 $\pm$ 1.2	1.248
MCHC (g/dl)	31.8 $\pm$ 1.8	31 $\pm$ 1.5	0.9

Table 2: Serumelectrolytes in the infected, non-infected and local chickens

Parameters	Infected	Non-infected	L.S.D
Na (mm/l)	125± 4.2	130± 2.9	2.641
K (mm/l)	5.6± 0.7	6.0± 0.5	0.201
Ca (mm/l)	2.0± 0.9	0.8± 0.6	0.321
CL (mm/l)	99± 3.0	108± 3.2	2.12

Table 3: Serum biochemical parameters in the infected, non-infected and local chickens

Parameters	Infected	Non-infected	L.S.D
GPT (IU/L)	22.1 ± 1.7	25± 1.8	1.899
GOT (IU/L)	31.0 ± 2.5	35± 1.9	1.965
ALP (IU/L)	164.8 ± 23	180± 2.7	2.651
Creatinine (mg/dl)	0.91 ± 0.20	1.2± 0.6	0.231

## DISCUSSION

Hematological and biochemical analyses are essential to monitor the health status of poultry in general and Broilers in particular, although rarely offer sufficient information to outline an etiologic diagnosis. In many species of mammals and birds, clinical and laboratory diagnosis is based largely on the results of hematological and biochemical investigations [12]. The pattern of blood parameters for infection chickens are different from the pattern observed in non-infection- chickens and suggested that this was due to the circadian variation in plasma volume, or to activity [17]. Activity is probably not responsible for the pattern observed in the present study, as the local chicken remain active from morning till about 1800 hr, after they start to prepare to roost [13]. This variation may be related to the increased metabolic activity needed to meet the energy demands for both maintenance and growth under relatively extreme stressful conditions [14]. The decrease in  $\text{Na}^+$  concentration might be related to concurrent loss of  $\text{Na}^+$  and water due to loss of water from the body that causes decreased extracellular fluid volume [15]. Variation in creatinine reflects degree of muscular activity. The significant variation observed in serum creatinine in this study, as the local chicken engages in marked muscular activity throughout the day [18]. Three of the four serum enzymes measured in the present study, exhibited robust [16]. The emergence of inflation and bloating to the presence and concentration of large numbers of tapeworms and round worms in the intestines as well as the presence of nodules small nodules with a rough texture on the walls. The interior of the gut, as well as hyperplasia who gets in epithelial cells increases the size of the intestines as well as infiltration of inflammatory cells in the intestinal walls adds increase in size, which leads to pressure on the intestine walls and thus get inflation and swelling in the intestine walls [19,20]. The occurrence of inflammation and the destruction and alienation tops Villi in places parasite adhesion to the intestinal wall [21]. The emergence of pathological lesions in the intestines accompanied occurrence of bloody diarrhea due to erosion and the migration of parasite in the intestinal wall and adhesion layers of the intestine, making it easy movement and access to the deep layers of the intestine, the adhesion of parasites in the gut leads to a Erosions in the epithelial cells of the gut [8]. Parasite regarded as a foreign body needs to defend before Body seen in the form of infiltration of defensive cells inflammatory cells, especially acidic Eosinophile. That Occurrence of degeneration in the current study is consistent with what has been recorded, in the intestines of infected chicken's parasite. Interpreted occurrence of degeneration caused by the presence [19]. Parasite in the intestine leads to the disintegration of the villi Where the exits, and devoid of any erosion of the original landmarks epithelial cells lining the intestinal villi and glands show [20].
