ABSTRACT

This work is an attempt to study the in-vitro anti-diabetic and antioxidant activity along with the analysis of phytochemical constituents of liverworts Ptychanthus striatus (Lehm. & Lindenb.) Nees (Lejeuneaceae), Pellia epiphylla (L.) Corda (Pelliaceae) and Bazzania oshimensis (Steph.) Horik. (Lepidoziaceae). Antioxidant activities were analyzed in-vitro by seven different assays: DPPH radical, metal chelating, superoxide, ABTS⁺, reducing power, anti-lipid peroxidation and nitric oxide assay. Anti-diabetic potential was analysed by estimating α-amylase and α-glucosidase inhibitory activity of the plant. Detection and estimation of the constituent phytochemicals was done through qualitative test, quantitative test and TLC analysis. Results indicated significant anti-diabetic activity, antioxidant activity and occurrence of varied phytochemicals in studied plants. This finding paved the way for further analysis on these liverworts for obtaining phytochemicals of significant clinical and cosmetic importance.

Keywords: Anti-diabetic, antioxidant, phytochemicals, liverworts, TLC

INTRODUCTION

Diabetes mellitus (DM) is one among the major worldwide health problems of 21st century. Either incapability of pancreas to produce enough insulin (T1DM) or failure of body cell to respond to insulin (T2DM) results in diabetes [1]. Oxidative stress plays major role in both insulin secreting β-cell dysfunction and insulin resistance [2]. Multiple sources of oxidative stress are identified, viz. non-enzymatic, enzymatic and mitochondrial pathways. Non-enzymatic sources are: i) auto-oxidation of glucose generating •OH radicals ii) glucose protein reaction during non-enzymatic glycation producing advanced glycosylation end products (AGEs) and iii) enhanced metabolism of glucose through polyol pathway resulting in O₂•− production [3]. Generation of O₂•− during mitochondrial respiratory chain is another non-enzymatic source of reactive species (RS) [4]. Persistent elevated hyperglycemia enhances glucose flux through glycolysis and tricarboxylic acid cycle and leads to an overdrive of mitochondrial electron transport chain and elevation of proton gradient, resulting generation of more O₂•− than mitochondrial antioxidant enzyme superoxide dismutase (SOD) can dismute. Enzymatic sources are enhanced activity of nitric oxide synthase (NOS), NAD(P)H oxidase and xanthin oxidase generating greater RS [3]. RS cause insulin resistance and disinfection of insulin secreting β-cells as they are low in free radical quenching enzymes like superoxide dismutase, catalase and glutathione peroxidase [5]. Antioxidants can, therefore, be considered effective in reducing increased blood sugar level [1]. Two enzymes α-amylase and α-glucosidase play key role in diabetes. By inhibiting these enzymes, the rate of glucose absorption and post-prandial blood sugar levels can be reduced.

Herbal remedies for diabetes and other oxidative stress related diseases are favoured due to least side effects [6]. Liverworts with its record of being used in several traditional medicine [7], have so far lagged behind in terms of exploration of its pharmacological activity and phytochemical constituents. Life strategies of bryophytes are considered to be the system of co-evolved adaptive qualities. They can survive extreme environmental conditions.
Most plants die when their relative water content falls below 20-50%. Only few plants, including bryophytes, can dry up to 4-13% and can still be resurrected and hence are referred as the desiccation tolerant plants [8]. During extreme dryness, they enter a stage of little intracellular water and almost no metabolic activity resulting in irreversible damage to lipids, protein and nucleic acids through production of RS. One of the important strategies shown by desiccation tolerant plants to limit damage to a repairable level is the production of antioxidants [9]. Considering that bryophytes can survive extreme climate and resurrect under favourable condition, it is assumed that this group of plant might possess strong antioxidative mechanism. Thus, in this work an attempt has been made to study the antioxidative and anti-diabetic activity along with phytochemical content of three important liverworts namely Ptychanthus striatus, Pellia epiphylla and Bazzania oshimensis. To our knowledge, present study is the first report detailing antidiabetic activity and phytochemical constituents of P. striatus, P. epiphylla and B. oshimensis found in the Darjeeling hills of Eastern Himalaya, India.

EXPERIMENTAL SECTION

Collection and identification
Liverwort samples were collected from Sinchel, Darjeeling in the month of July, 2013. The taxonomic identification was done by Dr. D.K. Singh, Scientist G and Dr. Devendra Singh Scientist C, Botanical Survey of India, Kolkata and voucher specimens have been deposited in the Central National Herbarium of the Botanical Survey of India, Howrah, India (CAL).

Animal material
Goat liver used for anti-lipid per oxidation assay was collected immediately after slay from slaughter house and experiment was conducted within 1 hour.

Chemicals used
Methanol (M), 2.2-diphenyl-1-picryl hydrazyl (DPPH), reduced nicotinamide adenine dinucleotide sodium salt monohydrate (NADH), nitro blue tetrazolium (NBT), sulfanilamide, phenazine methosulphate (PMS), ferrous chloride, trichloroacetic acid (TCA), ferrozine, thiobarbituric acid (TBA), glacial acetic acid, naphthylethylene diamine dihydrochloride, FeSO_4.7H_2O, potassium dihydrogen phosphate (KH_2PO_4), potassium hydroxide (KOH), potassium ferricyanide, ethylene-diamine tetraacetic acid (EDTA), 2-deoxyribose, ferric chloride (FeCl_3), hydrogen peroxide (H_2O_2), sodium nitroprusside, gallic acid, Folin-Ciocalteu reagent, sodium carbonate (Na_2CO_3), sodium nitrite (NaNO_2), ninhydrin, lead acetate, aluminium chloride (AlCl_3), petroleum ether, copper acetate, chloroform, sodium hydroxide (NaOH), sulphuric acid, Dragendorff’s reagent, hydrochloric acid, pyridine, α-glucosidase, α-amylase, pNPG (p-Nitrophenyl-α-D-glucopyranoside) were either purchased from Sigma Chemicals (USA) or of Merck analytical grade.

Methods of extraction
Collected liverworts were cautiously inspected to remove soil and other plant materials attached to it. As different species grow in close association with each other, sample of interest is cautiously separated from other associated taxa. It was then washed, air dried, crushed into powder and extracted with methanol.

Anti-diabetic assay
α-Glucosidase inhibitory activity
Alpha-glucosidase inhibitory activity was assessed according to the method described previously [10], with few modifications. Reaction was initiated by incubation of 2.5 ml phosphate buffer, reduced glutathione and 0.1 ml enzyme for 15 min followed by addition of 0.5 ml sample and 0.25 ml P-NPG. The mixture was then left for 15 minutes and finally reaction was stopped by adding 0.1 M Na_2CO_3. The absorbance was taken at 405 nm and the α-glucosidase inhibitory activity was calculated using formula:

\[
\% I = \left(1 - \frac{A_s - A_b}{A_c}\right) \times 100, \text{ where}
\]

As = absorbance of sample, Ab = absorbance of blank, Ac = absorbance of control.

α- Amylase inhibitory activity
Method of Kim et al. [10] with few modifications was followed to study α- amylase inhibitory activity. Aqueous extract at various concentrations, 0.02 M sodium phosphate buffer containing α- amylase and starch were mixed and incubated for 10 min. The reaction was terminated by 1 ml dinitrosalicylic acid. Absorbance was measured at 540 nm by the following formula:

\[
\% I = \left(\frac{A_{540} - A_{540} E}{A_{540} C}\right) \times 100, \text{ where}
\]
Determination antioxidant activity

DPPH (2,2-diphenyl-1-picrylhydrazyl) radical scavenging activity
DPPH scavenging activity was estimated by the method of Sidduraju et al. [11]. To 200 µl extract 2 ml DPPH solution was added and the reduction in solution colour was measured spectrophotometrically at 517nm. Scavenging activity of the sample was calculated by using following formula:

\[ \% I = \left( \frac{A_0 - A_1}{A_0} \right) \times 100, \]

\( I \) = inhibition, \( A_0 \) = absorbance of blank, \( A_1 \) = absorbance of test sample.

Nitric oxide (NO) scavenging activity
Nitric oxide scavenging activity was estimated following earlier method [12] with few modifications. To 2 ml sodium nitroprusside, 0.5 ml phosphate buffer and 0.5 ml extract were mixed and incubated at 25°C for 150 minutes, then 3 ml Griess reagent was added and allowed to stand at room temperature for 30 minutes. The absorbance was measured at 540 nm. Nitric oxide scavenging activity was calculated by the following formula:

\[ \% I = \left( \frac{A_0 - A_1}{A_0} \right) \times 100, \]

\( A_0 \) = absorbance of control and \( A_1 \) = absorbance of sample.

Superoxide radical (SO) scavenging assay
Superoxide scavenging activity was analysed following the method of Fu et al. [13] with few modifications. 1 ml sample and 1 ml nitroblue tetrazolium chloride, 1 ml nicotinamide adenine dinucleotide and 10 µl phenazine methosulphate were mixed and incubated for 30 min under fluorescent light. Absorbance was measured at 560 nm. Superoxide scavenging activity was estimated by using following formula:

\[ \% I = \left( \frac{A_0 - A_1}{A_0} \right) \times 100, \]

\( A_0 \) = absorbance of control and \( A_1 \) = absorbance of sample.

ABTS\(^+\) (2,2-azino-bis(3-ethylbenzthiazoline-6-sulphonic acid) scavenging assay
ABTS\(^+\) scavenging activity was studied by slightly modified method of Li et al. [14]. 1 ml sample and 2 ml ABTS\(^+\) solution was incubated for 10 minutes. Scavenging activity was calculated based on percentage inhibition of absorbance at 734 nm by using formula

\[ \% I = \left( \frac{A_0 - A_1}{A_0} \right) \times 100, \]

\( A_0 \) = absorbance of control and \( A_1 \) = absorbance of sample.

Metal chelating assay
Method of Dinis et al. [15] with slight modification was implemented for metal chelating activity estimation. 400 µl sample, 1.6 ml methanol, 40 µl of FeCl\(_2\) and 80 µl Ferrozine were mixed and kept for 10 minutes before measuring the absorbance at 562 nm. Metal chelating ability was measured using formula

\[ \% I = \left( \frac{A_0 - A_1}{A_0} \right) \times 100, \]

\( A_0 \) = absorbance of control and \( A_1 \) = absorbance of sample.

Reducing power assay
Iron reducing ability was studied by using Gulcin [16] method with few modifications. 1 ml sample, 2.5 ml phosphate buffer, 2.5 ml potassium ferricyanide were mixed and incubated for 20 min at 50°C. Then, 2.5 ml 10% trichloroacetic acid was added and centrifuged. 2.5 ml upper layer was collected, to this 2.5 ml of distilled water and 250 µl of 0.1% FeCl\(_3\) was added and absorbance was measured at 700 nm.

Lipid peroxidation assay
Lipid peroxidation inhibition activity was studied following standard method of Bouchet et al. [17]. Goat liver was homogenized with phosphate buffered saline. The assay mixture contained in volume 0.1 ml of FeSO\(_4\), 2.8 ml 10% liver homogenate and 100 µl sample. After 30 min incubation at 37°C, 1 ml reaction mixture was taken and to this, 2
ml of thiobarbituric acid-trichloroacetic acid was added and heated for 1h in water bath. Supernatant was used to measure absorbance at 535 nm. The percentage of lipid peroxidation inhibition was estimated using formula:

\[
\% I = \frac{(A_F - A_t)}{(A_F - A_0)} \times 100,
\]

where

\(A_0\) = absorbance of control, \(A_t\) = absorbance of sample and \(A_F\) = absorbance of Fe\textsuperscript{+2} induced oxidation.

### Preliminary phytochemical analysis

#### Total phenol estimation

Method of Kadam et al. [18] with few modifications was implicated for phenol estimation. To 1 ml sample, 1 ml 95% ethanol, 5 ml distilled water and 0.5 ml 50% Folin ciocalteau reagent were added followed by addition of 1 ml 5% Na\textsubscript{2}CO\textsubscript{3} after 5 min. The absorbance was measured at 725 nm. Standard curve was calibrated using different concentrations of gallic acid.

#### Total flavonoid estimation

Flavonoid content was estimated following method described by previous authors [19] with few modifications. 0.5 ml extract, 4 ml distilled H\textsubscript{2}O and 0.3 ml 5% NaNO\textsubscript{2} were mixed followed by the addition of 0.3 ml of 10% AlCl\textsubscript{3} and 2 ml of 1.0 M NaOH after 5 and 6 min respectively. Finally, 2.4 ml of distilled water was added and absorbance was measured at 510 nm. Standard curve was prepared using different concentrations of catechol.

#### 2.7.3 Ortho-dihydric phenol estimation

Method of Mahadevan and Sridhar [20] with minor changes was followed to estimate ortho-dihydric phenol content. 0.5 ml extract, 0.5 ml of Arnow’s reagent (10g each of NaNO\textsubscript{2} and sodium molybdate in 100ml H\textsubscript{2}O), 5 ml H\textsubscript{2}O and 1 ml of 1(N) NaOH were mixed. Absorbance was measured at 515 nm. Standard curve was prepared with different concentrations of catechol.

#### Qualitative phytochemical tests

Tests for steroid, tannin, triterpenoid, amino acid, resin, cardiac glycoside, alkaloid, flavonoid, reducing sugar, anthraquinones and glycosides were carried out according to the methods mentioned earlier in different literatures with few modifications [21, 22, 23, 24].

#### Thin layer chromatography

To screen the presence of secondary metabolites, TLC analysis (Silica gel 60 F\textsubscript{254} pre-coated plates, Merck, Darmstadt, Germany) was performed using different solvent system (CH\textsubscript{3}COOC\textsubscript{2}H\textsubscript{5}: CH\textsubscript{3}OH: H\textsubscript{2}O :: 100:13.5:10); (CH\textsubscript{3}COOC\textsubscript{2}H\textsubscript{5}: CH\textsubscript{2}O\textsubscript{2}: CH\textsubscript{3}COOH : H\textsubscript{2}O :: 100:11:11:26); (CHCl\textsubscript{3}: CH\textsubscript{3}COOH : CH\textsubscript{3}OH : H\textsubscript{2}O :: 64:32:12:8); (C\textsubscript{7}H\textsubscript{8}: CH\textsubscript{3}COOC\textsubscript{2}H\textsubscript{5} :: 93:7). The developed TLC plates were then air dried and observed at 254 nm and 366 nm UV light. It was then sprayed with different spraying reagent. Spray reagents used were: KOH reagent, Berlin blue, Dragendorff’s reagent, NP/PEG reagent, 10% ethanolic KOH, vanillin-sulphuric acid reagent, Fast blue salt reagent for detection of anthraglycoside, arbutin, alkaloids, flavonoid, coumarin, saponins and phenols respectively [25]. The movement of the phytochemical was determined by its retention factor \((R_f)\)

\[
R_f = \frac{\text{Distance travel by solute}}{\text{Distance travel by solvent}}
\]

#### Statistical analysis

All statistical analysis was performed using standard software SPSS (ver. 15.0). Data was expressed as mean ± standard deviation and its difference was compared using one-way analysis of variance (ANOVA). Duncan’s Multiple Range Test \((P \leq 0.05)\) was also used to find out the significant difference in values. Correlation and Principal Component Analysis was done by using XLSTAT 2009 (Addinsoft) and Smith’s Statistical Package.

### RESULTS AND DISCUSSION

Tight control of post ingestion glucose level is important therapeutic strategy for the management of diabetes. The inhibition of carbohydrate hydrolyzing enzyme, α-amylase and α-glucosidase is an important strategy to tackle diabetes. Several synthetic α-glucosidase and α-amylase inhibitors are in clinical use but their prices are high and have many side effects [26]. All the analysed plant in this work samples showed α-amylase and α-glucosidase inhibitory activity with the highest activity shown by \(B. oshimensis\) in both cases. Table 1 and Table 2 represent dose dependent α-glycosidase and α-amylase inhibition potential of \(P. striatus\), \(P. epiphylla\) and \(B. oshimensis\). It is hypothesized that higher polyphenol content of the extract of \(B. oshimensis\) might be responsible for this inhibitory
activity. Similar kind of finding was also reported by Saravanam and Parmelazhagan [27]. In DM patients during persistent hyperglycemia, low density lipoprotein oxidation by the overproduction of RS contributes to oxidative protein damage and, therefore, to the pathogenesis of diabetic’s complication like arteriosclerosis. All three studied liverwort extracts prevented oxidation of lipid (Figure 1). This property might be attributed to their ability to scavenge OH that causes peroxidation of lipid. *B. oshimensis* displayed lower IC\textsubscript{50} value compared to *P. epiphylla* and *P. striatus*, which implies that the former has better lipid peroxidation inhibitory potential.

As studies suggest that oxidative stress imposed by hyperglycemia induced RS play major role in the pathogenesis of T2DM, antioxidative therapies reducing oxidative stress can be effective in controlling diabetic complications [28]. Figure 1and 2 represents the potential of *P. striatus*, *P. epiphylla* and *B. oshimensis* to scavenge different free radicals that might be generated in the living system. On examination of antioxidant activity, studied plant extracts potentially scavenged DPPH radical. *B. oshimensis* extract showed high scavenging activity of DPPH radical, which might be attributed to their ability to donate electron or hydrogen radical to DPPH • and stabilize them. Similarly, ABTS radical scavenging activity is also greater in case of *B. oshimensis* than other two. The result suggests that plant extracts produce sufficient donor hydrogen molecules that reduce DPPH • and ABTS + radicals. Similar quantum of activity was also shown by moss *Polytrichastrum alpinum* [29].

Free ferrous ions are the most powerful pro-oxidants and thus its reduction is important for protection against oxidative damage and lipid peroxidation by Fenton reaction [27]. The metal chelating assay shows that *P. epiphylla* has higher chelating activity. Fe\textsuperscript{2+} and ferrozine forms complexes to generate hydroxyl radical, in this assay plant extract may have interfered in the complex formation resulting in above mentioned chelating effect. Superoxide is considered one among strongest radicals, as it acts as a precursor for other RS like H\textsubscript{2}O\textsubscript{2}, O\textsuperscript{2−} and OH• that are extremely reactive and capable of damaging bio-molecules of living system. Three liverwort sample scavenged superoxide in the following order *P. striatus > B. oshimensis > P. epiphylla*.

Reducing power is considered as an effective assay for assessment of antioxidant reducing potential. It is the ability to reduce Fe\textsuperscript{3+}-ferricyanide complex to Fe\textsuperscript{2+}. It is assumed that reductive ability of plant extract might be due to the presence of compounds that are electron donors having the capability to reduce oxidized Fe\textsuperscript{3+} to Fe\textsuperscript{2+} [30]. *B. oshimensis* have the highest capability to reduce oxidized Fe\textsuperscript{3+} to Fe\textsuperscript{2+} than other two plant samples. Nitric oxide (NO) is an important bio-molecule, but its sustained level is toxic to tissue. NO generates spontaneously from sodium nitroprusside in aqueous solution and reacts with oxygen to form nitrite (NO\textsubscript{2}−) anion. Scavengers of NO compete with oxygen to inhibit the formation of nitrite [31]. Present study demonstrated that the methanolic extract of *B. oshimensis* has better NO scavenging activity than *P. striatus* and *P. epiphylla*.

Study claims that phytochemicals especially phenols to be accountable for oxidative stress reducing ability [32]. An insight into chemical nature can present rich data in understanding correlation between phenolic compound and stress reducing ability. By qualitative analysis, the phytochemicals like steroid, tannin, triterpenoids, amino acids, resin, cardiac glycoside, flavonoids, reducing sugar and anthraquinones are proven to occur in all studied hepatics (Table 3). These secondary metabolites present in the plant are accountable for the displayed antioxidative [33] and α-glucosidase inhibitory [28] activity by such plants. TLC profiling provides impressive information regarding the
existence of different phytochemicals. TLC analysis of *P. striatus*, *P. epiphylla* and *B. oshimensis* further confirmed the presence of phenolic compounds like coumarin, alkaloid, anthraglycoside, arbutin, phenol and flavonoids (Table 4). Different phyto-compounds encompass unique Rₖ values in different solvent system providing an important clue in understanding their polarity.

The phytochemical screening indicated that the phenolic compounds to be major components of the liverwort extract. The quantitative estimation of crude chemical compounds present in the studied hepatics is summarized in Table 5. Quantification of total phenol, flavonoid and ortho-dihydric phenol demonstrated that *B. oshimensis* extract has higher phenol, flavonoid and ortho-dihydric phenol content compared to *P. striatus* and *P. epiphylla*. High phenolic compound content of *B. oshimensis* extract justifies the higher antioxidant activity showed by the plant. Flavonoids are considered as good inhibitors of α-glucosidase and also the regulators of oxidative stress induced diabetic complications [34]. Result from our work also supported this fact, where *B. oshimensis* with higher flavonoid content showed higher α-glucosidase inhibitory activity.

*Abbreviation used: Extractive weight (EWT), Total phenol (TPC), flavonoid (TFC) and ortho-dihydric phenol content (OPC)*
Data in the literature are sometimes contradictory regarding correlation between antioxidant activity of the plants and their polyphenol content. Strong correlation was observed between the two by some authors [28][35] while others observed no such correlation [36][37] or very weaker one only. From the Pearson correlation test (Table 6), significant positive correlation was absorbed between alpha glucosidase inhibitory activity and ABTS radical scavenging activity. While, flavonoid content and DPPH* scavenging activity; superoxide scavenging and metal chelating activity; reducing power and ABTS radical scavenging activity; reducing power and nitric oxide scavenging activity were found to be negatively correlated with each other. It is difficult to explain relationship between antioxidant activity and phenolic content using statistical tools because antioxidant potential of single compound within a group can differ extremely and thus an equal amount of phenolics doesn’t always show similar radical scavenging activity. Moreover different antioxidant assay used as well as synergism of antioxidant compounds with each other may also affect antioxidant activity significantly [38].

* Correlation is significant at the 0.05 level (2-tailed).

Abbreviation used: superoxide (SO), nitric oxide (NO), metal chelating (MC), Antilipid peroxidation (ALP), α-glucosidase (αG), α-amylase (αA)

Figure 3: Principal component analysis of radical scavenging activity, anti-diabetic activity and phenolic compounds
For better understanding of relationship among the analyzed variables, Principal Component Analysis (PCA) was applied. First two principal components (PC1 and PC2) obtained after statistical analysis accounted for 87.34% and 12.66% of the variance respectively. The loading plots of first and second principle components are shown in figure 3. The loading of PC1 had a strong correlation with in vitro anti-diabetic and radical scavenging but not with the phenolic compounds indicating these antioxidant and antidiabetic activity to be controlled by compounds other than phenolics. Whereas the Principal Component 2 (PC2) had a high correlation with reducing power and super oxide scavenging activity as well as total phenolic compounds.

CONCLUSION

Till date, higher group of plants like angiosperm have been mostly investigated for the drug development, but studies suggest that plants belonging to same group have similar phytochemical constituents. Thus for the discovery of new therapeutic substances, there’s a constant need to search for novel resources within unexplored group of plants like liverworts (bryophytes). At present, only about 5% percent of liverworts are chemically studied worldwide [39]. Similarly, in India only recently, studies have been initiated to screen the bioactivities as well as phytochemicals of liverworts. This work confirms the in vitro anti-diabetic and free-radical scavenging potential as well as the existence of versatile groups of bioactive phytochemicals in three liverworts namely P. striatus, P. epiphylla and B. oshimensis collected from Eastern Himalaya.
