ABSTRACT

The Mannich base -N-[1-morpholinobenzylacetamide] and its transition metal complexes with Ti (III), V (III), Mn (III), Fe (III), Co (III), MoO(V), Ru (III), Ru (II), MoO₂ (VI) and UO_2 (VI) have been synthesized. The ligand and its metal complexes have been characterized by M.P., elemental analyses and spectral studies. The ligand and the corresponding metal complexes were screened for their antibacterial activities.

Key words: Mannich base, transition metal & Antibacterial activity.

INTRODUCTION

Considerable interest has been shown on the synthesis of Mannich bases by conventional methods as well as by the use of microwaves [1] in the presence of solid supports. Many reports are available in the literature for the synthesis of Mannich bases using aliphatic and aromatic aldehydes [2-5]. It is well known from the literature that the compounds containing amide moiety have a strong ability to form metal complexes and exhibit a wide range of biological activities [6-8]. Keeping these facts in view, the present Mannich base has been synthesised and its complexation behaviour studied.

EXPERIMENTAL SECTION

All the chemicals and reagents used were of A.R. or equivalent purity, Benzaldehyde, Acetamide, morpholine and all the metal salts were procured from the reputed firms, while Ti (III) Chloride was prepared in the lab by reported method.

Preparation of the Mannich Base Ligand :

Acetamide in ethanol was mixed with morpholine and the mixture was treated with benzaldehyde in the ratio of 1:1:1. The reaction mixture was then kept at room temperature for five days. The solid obtained was filtered and recrystalised from ethanol.

Preparation of the Complexes

The solution of the Mannich base was added to the solution of the respective metal salt. A solid complex was obtained in each case. It was filtered washed and dried in vacuum dessicator. Ti (III) and V (III) complexes were prepared under the atmosphere of dry nitrogen gas, while all other complexes were prepared under normal conditions.

RESULTS AND DISCUSSION

The complexes are coloured solids except those of MoO_2 (VI), Ru (II) and UO_2 (VI). The elemental analyses of the complexes revealed 1:2 metal ligand ratio. The molar conductance values at 25^o and 10⁻³ M dilution, suggested 1:1 electrolytic nature for Ti (III), Mn (III), V (III), Fe (III), Co (III), Ru (III) and MoO (V) complexes while the complexes of Ru (II), MoO₂ (VI) and UO₂ (VI) were non electrolytes.

The measurement of magnetic moment by Gouy's balance suggested paramagnetic nature for Ti (III), V (III), Fe (III), Ru (III) and MoO (V) complexes while the complexes of Ru (II), Co (III), MoO(VI) and UO₂ (VI) were diamagentic in nature.

Electronic spectra & Magnetic Moment:

The Ti (III) complex shows magentic moment of 1.70 B.M. This value is closed to the calculated value for d¹ system (1.73 B.M.) like Ti (III) and show paramagentic character for the complex. The electronic spectrum of the complex shows a single band at 19600 cm⁻¹, which may be assigned to ${}^{2}T_{2g} \rightarrow {}^{2}E_{g}$ transition [9]. This is characteristic of Ti (III) octahedral complex.

The magnetic moment of the vanadium (III) complex is 2.94 B.M. which is nearly equal to the calculated value for d^2 system like V (III). The electronic spectrum of V (III) complex exhibited band at 16200 cm⁻¹ and shoulder at 20800 cm⁻¹. The low energy band may be assigned to the ${}^{3}T_{1g}(f) \rightarrow {}^{3}T_{2g}(f)$ transition in octahedral symmetry and high energy band to ${}^{3}T_{1g}(f) \rightarrow {}^{3}T_{1g}(p)$ transition[10].

The magnetic moment of Ru (III) complex is 1.94 B.M. The electronic spectrum shows bands at 10330, 16129, 24390 and 35087 cm⁻¹ may be assigned to the transition ${}^{2}T_{2g} \rightarrow {}^{4}T_{1g}$, ${}^{2}T_{2g} \rightarrow {}^{4}T_{2g}$, ${}^{2}T_{2g} \rightarrow {}^{2}A_{2g}$, ${}^{2}T_{1g}$ and $\pi \rightarrow T_{2g}(\pi^*)$ levels respectively [11]. These are characteristic of an octahedral geometry.

The Ru (II) complex is diamagnetic in nature. The electronic spectrum of the complex in CH_2Cl_2 shows a band assigned to the charge transfer transition arising from the excitation of an electron from the metal t_{2g} level to the unfilled molecular orbitals derived from the π^* level of the ligand in accordance with the assignments made for other similar octahedral ruthenium (II) complex [12-14].

The magnetic moment of Mn (III) complex is 4.90 B.M. which is in expected range for d⁴ system like Mn (III) and suggested paramagnetic nature for the complex and revealed high spin nature of the complex. It supported octahedral symmetry. Unusually Mn (III) has ⁵D electronic ground state and in an octahedral symmetry, a single absorption band is expected due to spin allowed transition ${}^{5}E_{g} \rightarrow {}^{5}T_{2g}$ however even for symmetrical ligand field, they are subject to Jahn-Teller distortion for high spin d⁴ configuration [15].

The complex shows two bands assignable to ${}^{5}B_{1g} \rightarrow {}^{5}T_{2g}$ at 18500 cm⁻¹ transition and other band at 25000 cm⁻¹ may be assigned to Mn \rightarrow (d π) - π *(azomethine [16].

The magnetic moment of Fe (III) complex is 5.97 B.M. corresponding to five unpaired electron and high spin state of Fe(III) ion. Three bands have been observed in the electronic spectrum of the complex at 11235, 21740 and 27780 cm⁻¹ assignable to ${}^{6}A_{1g} \rightarrow {}^{4}T_{1g}$, ${}^{6}A_{1g} \rightarrow {}^{4}T_{2g}$ and ${}^{6}A_{1g} \rightarrow {}^{4}E_{g}$ transitions respectively suggesting an octahedral geometry [17].

The magnetic study of Co (III) complex indicated diamagnetic nature for the complex, as expected for low spin d⁶ ion.

The electronic spectrum shows bands at 15140, 21110 and 23330 cm⁻¹. These bands have been assigned to ${}^{1}A_{1g} \rightarrow T_{2g}$, ${}^{1}A_{1g} \rightarrow {}^{1}T_{1g}$ and ${}^{1}A_{1g} \rightarrow {}^{1}T_{2g}$ transitions respectively [18].

The magnetic moment of MoO(V) complex is 1.70 B.M. which is very near to calculated value for one unpaired electron. The electronic spectrum shows bands at 14200, 19610 and 25000 cm⁻¹ which have been assigned to ${}^{2}B_{2}$ ${}^{2}E$ (dxy→dxz - dyz), ${}^{2}B_{2}$ → ${}^{2}B_{1}$ (dxy→dx² - dz²) and ${}^{2}B_{2}$ → ${}^{2}A_{1}$ (dxy-dz²) transitions respectively. The complex can be best considered as octahedral with strong tetragonal distortion (C_{4r} symmety) resulting from Mo=O bond [19].

The electronic spectrum of MoO₂(VI) & UO(VI) complexes show only charge transfer band.

Infra Red Spectra :

The IR spectra of the ligand and its metal complexes were recorded in KBr phase and compared in order to find out the possible coordination sites. The IR spectrum of the ligand showed bands at 3380, 1600 and 1100 cm⁻¹ assignable to v(N-H), amide v(C=O) and v(C-N-C) of morpholine respectively. In the IR spectra of the complexes, the band due of v (N-H) appeared almost unchanged, excluding the possibility the coordination through this group. The amide v (C=O) and v(C-N-C) bands showed substantial negative shifts, indicating coordination through oxygen atom of amide moiety and nitrogen of morpholine entity present in the ligand (8). These coordination sites were further supported by the appearance of non-ligand bands in the for IR region of the complex at 510 and 465 cm⁻¹ assignable to v M-O and v M-N vibrations respectively [20].

Table-1

Note : The cocld. values are given in brackets.

The IR spectra of the complexes showed some other non ligand bands in the region of 3490-3510 cm⁻¹ attributable to vO-H of water molecule. The coordinated nature of these water molecules is suggested by two other non-ligand bands in the regions of 835-850 cm⁻¹ and 740-750 cm⁻¹ due to wagging and rocking modes. The coordinated nature of water molecules in further supported by TGA. The loss of water molecules accused in the temperature range of $170-190^{\circ}$ C. In UO₂(VI), bands at 910 and 930 cm⁻¹ indicated linear character of UO₂group. In the case of MoO(V) complex, the bands at 950 cm⁻¹ may be assigned to Mo = O moiety. The bands at 960 and 910 cm⁻¹ in MoO₂ (VI) complex suggested is nature of O=Mo=O moiety.

The NMR spectra of the ligand exhibited an absorption peak at 6.2δ and 10.1δ assignable to N-H proton and to N=C-OH proton respectively. The disappearance of these peaks in the complex indicated the coordination via the dissociation of -OH proton of the ligand. The signal due to morpholine v-CH₂ proton at 2.6\delta also shifted down field, suggesting coordination of morpholine nitrogen.

CONCLUSION

On the basis of studies performed an octahedral geometry may be proposed for all the synthesised complexes, with possible distortion due to Mo=O moiety in the case of MoO(V) complex.

M= Ti(III), V(III), Co(III), Fe(III), Ru(III) or Mn(III)

Antibacterial Activity:

The ligand and few of its metal complexes were tested for antibacterial activity. Muller Hinton agar was used for testing the susceptibility by well diffusion method (20) using DMSO as solvent, at a concentration of 0.01 M Gram positive and Gram negative bacteria. The zone of inhibition was determined at the end of incubation period of 24h at 37^oC. The metal complexes appeared to be more potent than the ligand (Table-2). Ampicelin was used as standard.

Compound	S.aureus	E. coli	P. auroginosa	B. subtitis
